

Objectives

- Explain the need and Benefits of component life cycle
- Identify various life cycle hook methods
- List the sequence of steps in rendering a component

In this hands-on lab, you will learn how to:

- Implement componentDidMount() hook
- Implementing componentDidCatch() life cycle hook.

Prerequisites

The following is required to complete this hands-on lab:

- Node.js
- NPM
- Visual Studio Code

Notes

Estimated time to complete this lab: **60 minutes**.

1. Create a new react application using *create-react-app* tool with the name as “blogapp”
2. Open the application using VS Code
3. Create a new file named as **Post.js** in **src folder** with following properties

```
1 class Post {
2   constructor(id, title, body) {
3     this.id = id;
4     this.title = title;
5     this.body = body;
6   }
7 }
8
9 export default Post;
```

4. Create a new class based component named as **Posts** inside **Posts.js** file

A screenshot of a code editor window titled 'JS Posts.js'. The editor shows the following code:

```
1 class Posts extends React.Component {  
2   constructor(props){  
3     super(props);  
4   }  
5 }
```

Figure 1: Posts Component

5. Initialize the component with a list of Post in state of the component using the constructor
6. Create a new method in component with the name as **loadPosts()** which will be responsible for using Fetch API and assign it to the component state created earlier. To get the posts use the url (<https://jsonplaceholder.typicode.com/posts>)

```

import React, { Component } from "react";
import Post from "./Post";

class Posts extends Component {

  constructor(props) {
    super(props);

    this.state = {
      posts: []
    };
  }

  loadPosts = () => {

    fetch("https://jsonplaceholder.typicode.com/posts")
      .then(response => response.json())
      .then(data => {

        const posts = data.map(
          item => new Post(item.id, item.title, item.body)
        );

        this.setState({
          posts: posts
        });

      })
      .catch(error => {
        throw error;
      });

  }

  componentDidMount() {
    this.loadPosts();
  }

  componentDidCatch(error, info) {
    alert("Error : " + error);
  }

  render() {

    return (

      <div>

```

```

    <h1>Posts</h1>

    {
      this.state.posts.map(post => (

        <div key={post.id}>

          <h3>{post.title}</h3>

          <p>{post.body}</p>

          <hr />

        </div>

      ))
    }
    </div>

  );
}

}

export default Posts;

```

7. Implement the **componentDidMount()** hook to make calls to **loadPosts()** which will fetch the posts

```

class Posts extends Component {

  constructor(props) {
    super(props);

    this.state = {
      posts: []
    };
  }

  loadPosts = () => {

    fetch("https://jsonplaceholder.typicode.com/posts")
      .then(response => response.json())
      .then(data => {

        const posts = data.map(
          item => new Post(item.id, item.title, item.body)
        );

        this.setState({
          posts: posts
        });

      })
      .catch(error => {
        throw error;
      });

  }

  componentDidMount() {
    this.loadPosts();
  }

  componentDidCatch(error, info) {
    alert("Error : " + error);
  }

  render() {

    return (

      <div>

        <h1>Posts</h1>

```

```

    {
      this.state.posts.map(post => (

        <div key={post.id}>

          <h3>{post.title}</h3>

          <p>{post.body}</p>

          <hr />

        </div>

      ))
    }
  </div>

);
}

}

export default Posts;

```

8. Implement the **render()** which will display the title and post of posts in html page using heading and paragraphs respectively.
9. Define a **componentDidCatch()** method which will be responsible for displaying any error happening in the component as alert messages.

Figure 2: componentDidCatch() hook

10. Add the Posts component to App component.
11. Build and Run the application using *npm start* command.
